# Morphological processing in the pre-literate bilingual brain

Xin Sun, Chloe Siu\*, Janice Chen\*, Hélène Deacon & Janet Werker

\*Chloe Siu and Janice Chen contributed equally to the work

## Introduction

- Morphological awareness, or the ability to understand and make use of word morphemes, plays an essential role in language and literacy development
- Children begin to show awareness of morphemic units from 4 years old, before they learn to read<sup>1</sup>
- •Reading-age bilingual children develop specialized neurocognitive mechanisms to process multi-morphemic words<sup>2</sup>
- •It remains *unknown* if these differences in brain functions between bilingual and monolingual readers come from their experiences with the written language, or if they have their origins before they learn to read

# Question

How does the developing brain *begin* to support bilingual and monolingual children's emerging understanding of word morphemes prior to learning to read?

## Method

#### Participants to date

N = 12 (5 bilinguals, 6 girls)  $M_{Age} = 4.90$  (4.17-5.58)

#### **Experimental Task**

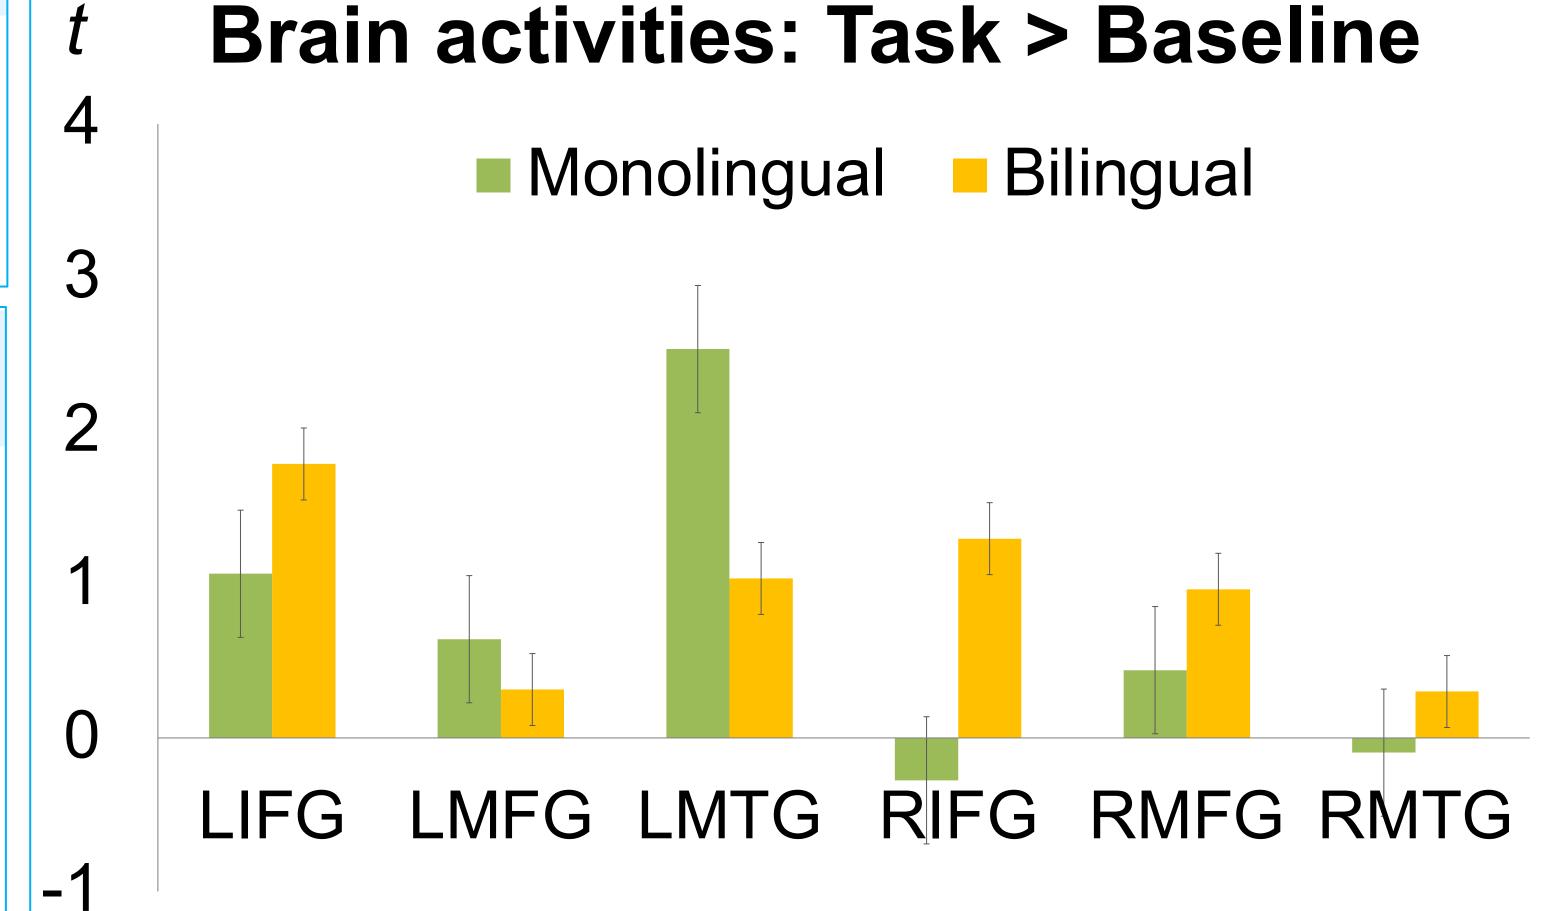

# fNIRS setup and preliminary results

fNIRS setup on a monolingual child

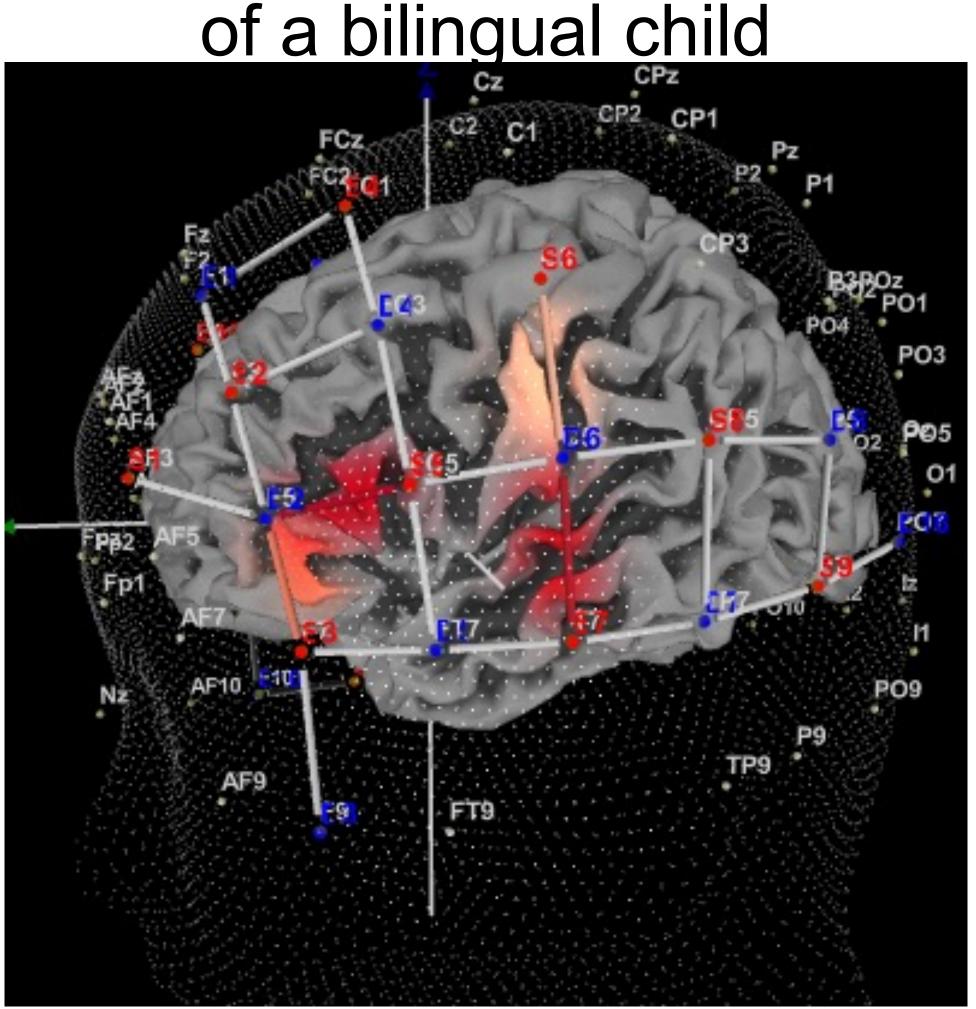

#### D...!.. - -1!..!1! - - - T. - | - - - | - - - | 1!...

Task > Baseline activation

of a bilingual child

- Overall, the morphological task activated children's *inferior frontal* and *middle temporal regions*, which was also found in reading-age children<sup>2,3</sup>
- Bilingual children engaged more bilateral inferior frontal, whereas monolingual children engaged more left middle temporal regions

## Conclusion

The preliminary results suggest that, at pre-literate ages, early bilingualism may influence children's neural organizations for morphological processes.
